RMA for Final Project

Considerations:

- 3 services will be used, 2 AMP and 1 SMP running as best effort.
- So far the worst case execution time was a rough estimate, the project has just begun there isn't any kind of optimization, nonetheless, it will serve as a good estimate of the WCET.
- Pi has 4 cores
- For AMP cores FIFO will be used.

S1: Image Capture
WCET = 2
T = 25
D = 25
Core = 2 using AMP

S2: Image Process
WCET = 2
T = 50
D = 50
Core = 2 using AMP (Will try the same core in the beginning but it's not set in stone, will see on the 10Hz project)

S3: Image Save
WCET = 10
T = 100
D = 100
Core = 3, will let linux handle this core, I spec the most difficulty to be in this service, writing to flash is VERY slow, a RAM disk could be used but can also keep in mind that when we write a file in linux it is first wrote to a buffer and that is pretty fast the problem is when we go from buffer to flash.
